Assessing the Feasibility of Establishing a Commercial Greenhouse in Norman Wells, NT
Prepared by: Kimberley Sellwood & Jessica Dutton

April 2016
Executive Summary

This report provides the results of the NWT CanGrow Greenhouse Feasibility study for the Norman Wells case study. The feasibility study adapted tools and techniques for designing a commercially viable greenhouse for use in a northern setting. The study focused on addressing the community first – including local preferences, demand and growing conditions – and developing greenhouse design and business model planning around these community factors. The research team used in-depth feasibility analysis to develop recommendations for operating a successful commercial greenhouse in each community.

This report uses the data collected in Norman Wells to assess community readiness, make design recommendations, calculate the commercial feasibility of the endeavor, and assess the contributions that a commercial greenhouse can make as a social enterprise. The results reported refer to the first year of the proposed operation and guidance for expanding the operation in future years is provided throughout the report.

The proposed greenhouse would be 2160 sq ft. Hydroponic systems with built-in drip irrigation would be used to grow crops and radiant heating would be used to maintain temperature. A forced air ventilation system is required to circulate air and maintain temperature.

The report finds that a moderate revenue could be generated by a commercial greenhouse in Norman Wells. The most significant costs in the first year will be start-up costs. A large capital investment is recommended to establish the greenhouse and install an energy efficient radiant heating system. The proposed greenhouse would have the capacity to extend the growing season, offset imports and generate $59,656 in profit from sales in the first year.

Recommendations discussed include:

1. Greenhouse Design
   The proposed greenhouse is a 30ft by 72ft by 18ft arched greenhouse with 10ft sidewalls, polycarbonate end walls and double door entryway with a polyethylene glazing.

2. Crop Selection
   While the greenhouse design allows for plenty of room for expansion, the recommendation is to start with 8-10 crops: tomatoes, bell peppers, cucumbers, basil, cilantro, thyme, baby spinach, mixed greens, butter lettuce and romaine.

3. Growing Schedule
   The greenhouse design and proposed crops would be best served by a growing season that starts in April and ends in October.

4. Markets
   In its first year, the greenhouse is designed to grow enough produce to supply local catering company (Royal Mackenzie Catering) and a weekly Community Supported Agriculture (CSA) box for about twenty
members. In future years, the CSA membership can be expanded.

5. Heating
Two heating systems have been assessed for feasibility: forced air and radiant heat. If the capital money is available, radiant heat is strongly recommended to reduce energy costs.

6. Growing System
Hydroponic vertical growing towers and bato buckets are recommended because soil is not a readily available resource in Norman Wells, and shipping enough soil for a greenhouse of this size would be less efficient than growing without soil.

7. Bedding Plants
Bedding plants are a great source of revenue, as they are sold early in the year at a profit, leaving room to start other crops. It should be noted that a spring bedding plant sale would compete with the existing commercial greenhouse’s spring bedding plant sale.

8. Raised Beds
Permafrost zones vary widely in Norman Wells, therefore raised beds would be required for in-ground growing. While there is high demand for root vegetables, like potatoes, carrots, and onions, raised beds are not an efficient growing option for a greenhouse that would have to ship soil.

The study concludes that a commercial greenhouse designed according to the proposed model could be feasible in Norman Wells, particularly if funding was accessed to assist with start-up costs, especially equipment and capital. There is enough local support and demand for fresh produce, and it is possible to design a greenhouse that will be highly productive without accumulating high annual costs.

Introduction

Project Overview
The Aurora Research Institute developed the *NWT CanGrow Greenhouse Feasibility Study* to find out whether it is feasible to operate a commercial greenhouse in the Northwest Territories (NWT). NWT communities are interested in improving food security, increasing access to fresh and healthy produce, encouraging positive dietary choices and creating economic opportunities in local food production. Community growing initiatives have expanded across the north in recent years and a community of growers has emerged to support the budding NWT agricultural shift.

This study was supported by the Canadian Northern Economic Development Agency and the Government of the Northwest Territories Department of Industry Tourism and Investment. Like ARI, both agencies are interested in how commercial greenhouses can improve food security, economic opportunity and quality of life in NWT communities.

The feasibility study adapts tools and techniques for designing a commercially viable for use in a northern setting. The study tools are flexible enough to accommodate the differences between communities, which range from southern boreal to the high arctic. The feasibility study is focused on addressing the community first – including local preferences, demand and growing conditions – and developing greenhouse design and business model planning around these community factors. The research team examined two case studies – Inuvik and Normal Wells – and used in-depth feasibility analysis to develop recommendations for operating a successful commercial greenhouse in each community.

In February 2016, Kimberley Sellwood conducted data collection in Norman Wells to more accurately understand the local conditions, gather information about community readiness, and seek stakeholder input on the potential for a commercial greenhouse in the community. This report uses the data collected in Norman Wells to assess community readiness, make design recommendations, calculate the commercial feasibility of the endeavor, and assess the contributions that a commercial greenhouse can make as a social enterprise.

Reading the report
This report is intended for individuals or organizations in Norman Wells who may be involved with or are considering commercial greenhouse growing. This report is divided into four main parts: 1) Community Readiness, 2) Design Planning for a Feasible Greenhouse, 3) Accounting for a Feasible Greenhouse, 4) Greenhouses as Social Enterprise. The information provided in this document outlines the most feasible production schedule based on the feedback about produce needs, as sourced from community members, food retailers, organizations and institutions who are key players in the local food economy. It proposes a greenhouse design that can accommodate the production schedule that the community requires. It provides an overview of the projected costs and revenues that can be expected from the proposed greenhouse. Finally, the report considers the wider benefits that a commercial greenhouse can have within the community, as reported by local stakeholders.
Part 1: Assessing Community Readiness

The benefits of a local greenhouse are often quite apparent to those who hope to establish greenhouses in NWT communities. The community readiness assessment explores whether there is demand for a greenhouse in the wider community and whether the local markets can support the proposed operation.

Investigating the Market

Surveys and interviews were employed to explore the potential produce markets in Norman Wells. An online survey was circulated on Facebook and in-person to determine demand for fresh produce and interest in supporting a commercial greenhouse in the community. In total 91 surveys were collected, and interviews were conducted with the two grocery stores, one catering company, and the K-12 school that administers a subsidized foods program.

Even though the produce prices in Norman Wells are exceptionally high compared to more accessible regions in the north, community members surveyed still indicated they would be willing to pay a bit more for fresh, locally grown produce.

Royal Mackenzie Catering is a high volume catering company providing meals for 200 people a day at four locations. The owner reports that they order 1 ½ pallets of produce twice a week. Royal Mackenzie currently orders produce from Ramparts, but would be interested in amending her produce order to support a commercial greenhouse in Norman Wells.

Norman Wells residents who responded to the survey were strongly in favour of purchasing locally. Community Supported Agriculture (CSA) memberships provide an opportunity for community members to support local agriculture and receive a weekly box of fresh produce. A CSA is an agreement made between the grower and the customer to purchase a weekly subscription of produce. The rate for the veggie box is set in advance and full payment is taken at the beginning of the season, when growers need a large injection of funds to float seed and supply purchases. Weekly vegetable subscriptions are not only a consistent source of revenue, but can be expanded annually until your greenhouse achieves its growing capacity.

While the other local restaurants were not available to participate in the large volume customer interviews due to time constraints, it is advisable that a local grower pursue contracts with these markets. If the grower is able to come to an agreement, with the local restaurants amending crop production for the first year in lieu of a CSA membership is advisable.

The local grocery stores also provided feedback. The produce manager at the Northern store reported that, as a chain grocery store, they would not likely be able to purchase locally produced food. There is an opportunity for further discussion with upper management, once the greenhouse has a few seasons of production data demonstrating its capacity to provide fresh, consistent volumes of produce. In terms of market share, the Northern brings in two pallets of produce twice a week.

Ramparts, the independently owned grocery store in Norman Wells, brings in one pallet of produce twice a week. The produce manager reported that there may be an opportunity to supply the grocery store if the cost was competitive with southern suppliers, but the final decision would rest with the
owners. While the store is not included in the production schedule proposed in this report, excess yields at the end of each week could be sold to the store at below direct sale value.

Norman Wells does not have a local farmer’s market. However, it would be just as effective for a greenhouse operation to establish its own on-site, direct sales market on the weekend to sell excess crops after all other market obligations have been fulfilled.

Estimating Demand
Survey and interview data were analyzed to determine which markets are the most viable for immediate development, as well as those that do not seem like they would generate a reasonable revenue stream. In Norman Wells, the best market to supply in the first year of business, would be the local, large volume catering company Royal Mackenzie Catering. Also, with the goal of increasing its membership every year, a weekly vegetable subscription for 20 members is also incorporated into the crop production schedule.

Survey results show that community members are interested in some greenhouse produce, but also some produce that is better grown in-ground growing or raised beds. Greenhouse operations may consider adding beds inside or outside to expand capacity to support other crops.

Based on the results of the customer demand surveys and the reported demand from local restaurants, the proposed crops for the Norman Wells greenhouse are: tomatoes, cucumbers, bell peppers, herbs, spinach, mixed greens, green lettuce, and romaine.

**Bedding Plants**

Seventy-five percent of those surveyed said they were unaware that bedding plants were available for sale in the spring from the local commercial greenhouse. Fifty percent of those surveyed said they would buy bedding plants if they were available for purchase. This suggests a need for more strategic marketing, but also indicates there is room for growth. A commercial greenhouse could amend their production schedule to sell bedding plants early in the season, before they begin selling produce. There is a lot of opportunity in this market, as a wide selection of vegetable, herb and flower bedding plants are in demand.

Pricing Produce

Despite the already high prices of produce for sale in Norman Wells, more than half of the residents surveyed said they would be willing to pay a little bit more for fresh produce and only five percent of those surveyed felt the produce available is fresh (see Table 1). Generally, in the first year of operation, the commercial greenhouse need only to set prices that are close to the prices offered by current vendors in order to be competitive.

Produce in Norman Wells is in flown in twice a week. Both grocery stores reported very little lost revenue due to spoilage, but some community members reported produce tends to be soggy, as it is known to freeze during transportation. For this study, Ramparts and Northern produce prices were used as the benchmark. High-value or specialty crops, such as herbs and mixed greens are hard to transport up north, as they freeze easily. Therefore they can be sold for a premium, because they will be harvested and delivered within 24hrs; making them of the highest nutrient content and freshest produce available to the community.

The response from Norman Wells was overwhelmingly supportive of a commercial greenhouse. The key to moving forward is to ensure the crops made available by the greenhouse reflect the demand reported by the community. A schedule has been developed based on the information gathered in this section. Appendix C contains planning charts for each market that specify how much of each crop that market will consume each week throughout the growing season. Appendix D shows the weekly demand for each
crop from all markets – this is the total demand for each crop that the greenhouse will have to produce each week in order to supply all of the proposed markets.

Using the total number of units required each week to supply all proposed markets, the chart below summarizes the monthly activities (planting or harvesting) for each crop and number of units planted or harvested every week for the entire season. Crops are planted each week throughout the planting season and harvested each week during the harvesting season in order to provide a steady supply that matches the projected demand reported by customers.

To achieve these weekly targets, the greenhouse must have sufficient area to accommodate starting enough plants, weekly, to accommodate the harvests required for all markets. Appendix E contains the planning charts for space requirements by crop. Table 6 summarizes the growing area required for the proposed greenhouse. This includes area required for seedling trays, pots, and vertical hydroponic systems in each month.

</tbody>
</table>

*220ft is a static number for crops grown in bato buckets, as the same plants will continue to yield for the duration of the season*
Hydroponic systems were chosen for the proposed greenhouse design because they are an intensive growing model that focuses on getting the highest yield out of the smallest space. Bato buckets will be used to grow tomatoes, bell peppers and cucumbers (please see Part 2 for more details.) From the demand targets identified for all markets and the space requirements for each crop, the total growing area for the proposed greenhouse is 2160 square feet. This is double the growing area required for the first year in order that crop production can expanded in subsequent years. This will also allow area for workstations, washrooms, a point of sale area, and any other facilities that may be needed within the greenhouse itself.
Part 2: Design Planning for a Feasible Greenhouse

The previous section has established that there is significant support for a commercial greenhouse in the community. Part 2 explores the key design considerations that impact feasibility of commercial greenhouses. The following analysis will provide design recommendations and further planning details to ensure a feasible greenhouse.

Growing Systems

In order to have a feasible commercial greenhouse in Norman Wells, the proposed design plan must extend the growing season for as long as possible, while economically managing costs required to provide adequate heat and light to the crops. The objective of the proposed greenhouse design is to grow as late into the year as possible: crop production will begin in April and continue until the end of October.

Table 7: Summary planting and harvest dates by crop

<td>April 1st; plant every subsequent Sunday</td>
<td></td>
</tr>
</tbody>
</table>

The proposed design incorporates two growing systems to achieve the most economical production. As mentioned, bato buckets will be used to grow tomatoes, bell peppers and cucumbers. The buckets are filled with a soilless substrate. Nutrients are dripped into the top of the buckets and excess is drained out the bottom as waste water. The remaining crops will be grown in a vertical hydroponic system made up of grow towers (when linked together on a custom rack, this system is called a ZipFarm.) Like the bato buckets, the grow towers pump nutrients through the hydroponic solution.

Bedding plants can be an important addition to any commercial greenhouse operation. As mentioned above, the total growing area for the greenhouse is 2160 square feet, but this area is much larger than what’s required to grow the first year crops. This means expending resources to heat an unused space. Using that space to grow trays of bedding plants will generate $7-9 per square foot and ensure that valuable greenhouse space does not go to waste. Another option, if capital funding is available, would be to install separate closed system growing units that can produce crops all year-round.
Considering the demand requirements of the proposed markets and the space required for the proposed systems, the total growing area for the proposed greenhouse is 2160 square feet. This is double the space for the first year of production, but it means there is room for expansion.

**Glazing and Framing**

In addition to the crop type and space requirements discussed above, greenhouse design must consider the local conditions in order to create and maintain an optimal growing environment. The glazing and framing materials were chosen after a thorough consideration of Norman Wells’ two most serious challenges: high shipping costs and cold climate.

**Table 8: Glazing and Framing Recommendations**

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
<th>Transportation</th>
<th>Construction</th>
<th>Temperature</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kit</td>
<td>30’ x 72’ x 18’ arched roof greenhouse kit with 10ft sidewalls, twin wall polycarbonate end walls, double door entryway</td>
<td>Will transport easily in one shipment, reducing transportation costs</td>
<td>Designed for simple design, reducing construction costs</td>
<td></td>
</tr>
<tr>
<td>Glazing</td>
<td>Double inflated 6mm polyethylene glazing</td>
<td>Much lighter than triple or double polycarbonate</td>
<td>Less likely to be damaged during installation, draping process can be done by the grower, avoiding high construction costs</td>
<td>Adequate R-value (1.7), less prone to condensation issues</td>
</tr>
<tr>
<td>Framing</td>
<td>Galvanized steel</td>
<td>Fairly light for its strength – less support framework is required – reducing transportation costs</td>
<td>Very sturdy, generally has less support framework, reducing construction costs</td>
<td>Casts minimal shadow</td>
</tr>
</tbody>
</table>

The proposed greenhouse would be a kit consisting of galvanized steel covered with polyethylene glazing, except for two polycarbonate end walls. A triple or double wall of polycarbonate glazing offers the best insulating capability, however, it scratches easily and may not transport well. Also, if it is not properly installed, it is prone to serious condensation issues, which can cause fungal disease that wipes out crops quickly. Conversely, an inflated double wall of 6 mm polyethylene film has a similar R-value (insulating property) of 1.7 to a double wall of polycarbonate, but it is much lighter and damage-resistant.

One disadvantage of poly film is that it starts to become opaque over time, reducing light transmission and requiring replacement every 3-5 years. Still, the labour rate for replacement should be affordable because it is easy to re-glaze – many growers install the glazing themselves.
Temperature Needs

Heating the greenhouse in Norman Wells is not only the largest annual fixed expense, but it is also the key to optimal germination rates and even plant growth. Planning for this cost is critical to a commercial greenhouse’s success. Propane and natural gas are the typical fuel options for greenhouses, however these options are not available in Norman Wells, where heating oil is the primary fuel source. Seedlings will be started in the greenhouse in April and plantings will continue into September –Table 9 provides the average estimated fuel consumption per month.

</table>

These estimates are general projections. The greenhouse will likely only need 24 hour heat in April. In May, September and October it will be limited to overnight and in the early morning.

The most common approach for heating commercial greenhouses is to use forced air units and fans to circulate the warm air. The most efficient recommendation for a heating system is closed-looped water radiant heating. The initial investment will be especially high, because, as mentioned, heating fuel is not the norm for greenhouses. While Norman Wells has one of the lowest commercial heating fuel prices, it is still subject to high electricity rates and long winters. Once installed, radiant heating can reduce the monthly heating bill by thirty percent.

Table 10: Radiant Heat vs Forced Air

| Radiant Heat Advantages | Disadvantages | | Disadvantages |
|-------------------------|---------------|----------------|
| 1/3 the fuel cost of forced air | Initial investment is five times more than forced air | | An additional room (the storage room) would be necessary to house the boiler |
| Direct contact with soil means increased nutrient uptake | | | |
| Consistent temperatures equals more even crop growth | | | |
| Different temperature zones for flexible growing schedules | | | |
| Shorter production times | | | |
| **Forced Air Advantages** | | | |
| Minimal initial investment | It has the highest energy costs out of any system | | |
| Situated in the greenhouse, the units are hung from rafters | It is the most inefficient system, and needs additional fans to circulate the air around the greenhouse | | |
| | Hot air blown across the plant canopy is not ideal, and there is no additional heat being directed at the soil, where it is needed the most. | | |
The system includes rubber tubing that circulates hot liquid – water or glycol are options – to distribute heat. The tubing is laid underneath a concrete floor and through benches that will support seedling trays and bato buckets, to ensure seedlings are receiving enough heat for optimal germination. The benches would be arranged along either side of the greenhouse, with the vertical growing system running through the middle. The in-floor heating, combined with the radiant heating benches, will ensure that the soil is at 21C and the air is at 16C when the outside temperature is around -13 outside. A unit heater is recommended for back-up for when the temperature drops any lower.

**Light Needs**

Some greenhouse operations make use of supplemental light to extend the season or to grow year-round. The structure proposed for Norman Wells will transmit sufficient sunlight to establish seedlings in the early part of the season. In October, the sun does not rise until 9am and it sets at 8pm. Supplemental light shouldn’t be necessary, however, the grower may see a decrease in the final month yields.

By June, Norman Wells will have 24 hours of sunlight and the use of shade cloths will be essential for the cold hardy crops. Shade cloths should also be hung from both side walls in the evening to give all the crops a break from the sunlight. A typical strategy for shade cloths is to build a rack that the shade cloth is draped over, and the plants can grow underneath the cloth. This is a good option for the plants growing in the vertical system.

**Water Needs**

The current commercial rate for water in Norman Wells is .0122 cents/litre. A basic industry accepted standard for water consumption in greenhouses is 7-8 litres per square metre of growing area per day. The chart below gives the monthly estimates for water consumption for the greenhouse growing season.

Total: $553.46

**Energy Needs**

Fuel and electricity rates are the most cost prohibitive aspects of greenhouse production. Wherever possible, it is advisable to invest more money in energy efficient infrastructure up front and reap the benefits of a lower monthly energy consumption. This does require significant capital funding at the outset.
Electrical needs are estimated to consume approximately 10 – 15 percent of a grower’s total energy bill. The proposed greenhouse operates using three main systems: hydronic radiant heating, drip irrigation, and forced air ventilation. Table 1 outlines the electricity used by each system.

The energy use by these systems accounts for the minimum energy use for the greenhouse operation. If additional systems and appliances are added – for example, a computer system, a cash register, lights, power outlets, etc. – they will need to be factored in to the overall projected energy use.

The design recommendations in this section are closely tied to the local conditions and the needs of the crops that will be grown in the proposed greenhouse. A careful design outline has provided the necessary information to account, in detail, for all costs associated with the construction and operation of the proposed greenhouse operation. The next section will present a snapshot of the expected costs and revenues.
Part 3: Accounting for a Feasible Greenhouse

The previous section outlined the most efficient greenhouse design for the conditions in Norman Wells. Part 3 identifies the proposed greenhouse’s expected costs and possible revenue sources. The goal is to propose a greenhouse with balanced costs and revenues by limiting costs and maximizing efficiency.

Start-up Costs

The start-up costs for the proposed greenhouse include the purchase of all materials, systems, equipment, supplies and construction costs (including labour). Table 12 outlines, in detail, the start-up costs associated with the proposed greenhouse.

</table>
Start-up costs are the largest expense that a greenhouse operation will have to account for. Ideally, much of this cost would be covered by a funding injection, to reduce the financial burden on the grower and improve their chances for success. If capital funding to cover start-up costs cannot be found, the operation may still be feasible, provided the total start-up costs are not exorbitant.

**Consumable Costs**

Once start-up costs are accounted for, consumable item costs must be considered. This includes all direct inputs (planting containers, substrate, seeds, etc) and costs associated with sales (packaging for produce, storage, marketing, etc).

**Table 14: Consumable Item Costs**

**Fixed Costs**

Fixed costs are expenses you pay monthly or annually – the bills. The previous section of this report estimated fuel use for heating the greenhouse, electricity needs and water needs. These needs translate directly into estimated fixed costs. The chart below estimates the fixed costs for the proposed greenhouse during production months – please note, the greenhouse is only in operation for seven of twelve months. Annual costs have been divided amongst the seven months of operation.

**Table 15: Fixed Costs**

</tbody>
</table>
**Property Taxes/Leases**: a mill rate of 17.62 was used to calculate the estimated property tax of $65,000

**Insurance**: is a rough estimate for total liability

**Water**: see Table 12 for a breakdown of water estimates

**Energy**: estimated total cost for all systems calculated together for the entire season

**Fuel**: the total cost for natural gas for the season minus 30 percent savings anticipated with radiant heating system.

**Depreciation**: projected depreciation value of all equipment divided by expected lifespan.

**Labour**: The scale of greenhouse proposed in this report is large enough to need seasonal employees. The range of duties could span the entire season, from planting, to maintenance to harvesting and delivery. An estimate of 25 hours a week at $20.28/hr was used.

**Projected Sales**

Sales revenue is the profit the greenhouse operation generates from selling produce, and is calculated annually. Table 17 presents the projected annual revenue from each crop, based on the prices and unit targets set in the community readiness section.

<table>
<thead>
<tr>

</table>

*Depreciation is a cost that is kept in savings each year to account for any systems or items that break or must be replaced. The amount is calculated by the item’s value and its life expectancy.

Provided a grower is able to raise capital funds from federal, territorial, local and/or private funds, the proposed greenhouse can be feasibly established and even achieve modest profits in the first year. If operations are expanded in subsequent years, the grower can expect profits to increase.
Part 4: Commercial Greenhouses as Social Enterprises

Throughout the NWT, there is considerable interest in the wider social benefits that come from growing food locally. Commercial greenhouses can be very successful as a social enterprise that aims equally for commercial success, as well as maximal social benefits for the community.

**Local Economies**
By expanding the availability of locally produced food, a local greenhouse can displace southern imports, keeping money in the local economy and reducing dependence on outside suppliers.

During the growing season, the greenhouse will need to hire and train local people to assist with planting, caring for crops and harvesting. Through partnerships with local agencies, these jobs can offer an opportunity for local youth, Elders, underemployed individuals or marginalized groups to develop specific agriculture and technology skills.

**Healthy Eating Habits**
Greenhouse operators have an opportunity to promote their business while also promoting healthy eating. Healthy eating and cooking programs could be developed for the school food program. Hosting field trips at the greenhouse can be an opportunity to introduce children and youth to the basics of growing food. Greenhouse owners may be able to partner with local organizations access agriculture or health funding and coordinate healthy food programing, with excess produce from crops being incorporated into the program budget.

Employees are also a resource for spreading positive eating habits: the influence and knowledge gained through training and work experience could inspire them to choose fresh produce more often and encourage their family and friends to do so as well. When other community members see that fresh produce is turning up on tables and in conversation, they may be interested in trying produce that they had not previously been familiar with. Growers can offer further benefits by offering discounted CSA memberships to employees.

**Sustainable Food Systems**
By growing local foods, the greenhouse enterprise supports a locally sustainable food system. This is an important goal for northern communities, whose ties to southern food sources can often be precarious, sometimes relying on a single road that can be closed by forest fires, flooding, or weather.

A local greenhouse can also contribute to improving the local food system by teaching planting and growing in the community. This may be an opportunity to partner with other local organizations to access funds for programming that encourages local growing. The benefit is that community members will have a source of food, should they have limited income, or should usual food markets become unavailable in an emergency.
Recommendations

This report aims to provide a plan for a commercial greenhouse in Norman Wells a qualified grower could implement. The following are recommendations derived from the feasibility study.

1. Greenhouse Design
   The proposed greenhouse is a 30ft by 72ft by 18ft arched greenhouse with 10ft sidewalls, polycarbonate end walls and double door entryway with a polyethylene glazing.

2. Crop Selection
   While the greenhouse design allows for plenty of room for expansion, the recommendation is to start with 8-10 crops: tomatoes, bell peppers, cucumbers, basil, cilantro, thyme, baby spinach, mixed greens, butter lettuce and romaine.

3. Growing Schedule
   The greenhouse design and proposed crops would be best served by a growing season that starts in April and ends in October.

4. Markets
   In its first year, the greenhouse is designed to grow enough produce to supply local catering company (Royal Mackenzie Catering) and a weekly Community Supported Agriculture (CSA) box for about twenty members. In future years, the CSA membership can be expanded.

5. Heating
   Two heating systems have been assessed for feasibility: forced air and radiant heat. If the capital money is available radiant heat is strongly recommended to reduce energy costs.

6. Growing System
   Hydroponic vertical growing towers and bato buckets are recommended because soil is not a readily available resource in Norman Wells, and shipping enough soil for a greenhouse of this size would be less efficient than growing without soil.

7. Bedding Plants
   Bedding plants are a great source of revenue, as they are sold early in the year at a profit, leaving room to start other crops. It should be noted that a spring bedding plant sale would compete with the existing commercial greenhouse’s spring bedding plant sale.

8. Raised Beds
   Permafrost zones vary widely in Norman Wells, therefore raised beds would be required for in-ground growing. While there is high demand for root vegetables, like potatoes, carrots, and onions, raised beds are not an efficient growing option for a greenhouse that would have to ship soil.

<td>1</td>
<td>2 heads/ft</td>
<td>26ft/8ft = 4 towers</td>
<td>16 * 4ft2 = 64ft2</td>
</tr>
<tr>
<td>4th Week</td>
<td>51</td>
<td>1</td>
<td>2 heads/ft</td>
<td>26ft/8ft = 4 towers</td>
<td></td>
</tr>
<tr>
<td>Harvest Date: Oct</td>
<td>Units Harvested</td>
<td>RPB</td>
<td>YPF</td>
<td>GA Per Harvest</td>
<td>Monthly GA Required</td>
</tr>
<tr>
<td>1st Week</td>
<td>51</td>
<td>1</td>
<td>2 heads/ft</td>
<td>26ft/8ft = 4 towers</td>
<td>104ft of vertical growing area =</td>
</tr>
<tr>
<td>2nd Week</td>
<td>51</td>
<td>1</td>
<td>2 heads/ft</td>
<td>26ft/8ft = 4 towers</td>
<td>16 towers a month =</td>
</tr>
<tr>
<td>3rd Week</td>
<td>51</td>
<td>1</td>
<td>2 heads/ft</td>
<td>26ft/8ft = 4 towers</td>
<td>16 * 4ft2 = 64ft2</td>
</tr>
<tr>
<td>4th Week</td>
<td>51</td>
<td>1</td>
<td>2 heads/ft</td>
<td>26ft/8ft = 4 towers</td>
<td></td>
</tr>
</tbody>
</table>

Note: The calculations for the growing area and monthly required GA are based on the assumption that 1 tower requires 51.2 square feet (26ft/8ft = 4 towers) of growing area per week.
### Appendix F: Space Requirements for Seedling Trays

#### Crop: Tomato

<table>
<thead>
<tr>
<th>Planting Month</th>
